# KAFE

## 1.1 kafe Package

### 1.1.1 kafe Package

A Python package for fitting and plotting for use in physics lab courses.

This Python package allows fitting of user-defined functions to data. A dataset is represented by a *Dataset* object which stores measurement data as *NumPy* arrays. The uncertainties of the data are also stored in the *Dataset* as an *error matrix*, allowing for both correlated and uncorrelated errors to be accurately represented.

The constructor of a *Dataset* object accepts several keyword arguments and can be used to construct a *Dataset* out of data which has been loaded into *Python* as *NumPy* arrays. Alternatively, a plain-text representation of a *Dataset* can be read from a file.

Also provided are helper functions which construct a *Dataset* object from a file containing column data (one measurement per row, column order can be specified).

### 1.1.2 constants Module

`kafe.constants.F_SIGNIFICANCE = 2`

Set significance for returning results and errors  $N$  = rounding error to  $N$  significant digits and value to the same order of magnitude as the error.

`kafe.constants.G_PADDING_FACTOR_X = 1.2`

factor by which to expand  $x$  data range

`kafe.constants.G_PADDING_FACTOR_Y = 1.2`

factor by which to expand  $y$  data range

`kafe.constants.G_PLOT_POINTS = 200`

number of plot points for plotting the function

`kafe.constants.M_CONFIDENCE_LEVEL = 0.05`

Confidence level for hypothesis test. A fit is rejected if  $\chi^2_{\text{prob}}$  is smaller than this constant

`kafe.constants.M_MAX_ITERATIONS = 6000`

Maximum *Minuit* iterations until aborting the process

`kafe.constants.M_MAX_X_FIT_ITERATIONS = 2`

Number of maximal additional iterations for  $x$  fit (0 disregards  $x$  errors)

`kafe.constants.M_TOLERANCE = 0.1`

*Minuit* tolerance level

### 1.1.3 dataset Module

**class** kafe.dataset.**Dataset** (*\*\*kwargs*)

The *Dataset* object is a data structure for storing measurement and error data. In this implementation, the *Dataset* has the compulsory field *data*, which is used for storing the measurement data, and another field *cov\_mats*, used for storing the covariance matrix for each axis.

There are several ways a *Dataset* can be constructed. The most straightforward way is to specify an input file containing a plain-text representation of the dataset:

```
>>> my_dataset = Dataset(input_file='/path/to/file')
```

or

```
>>> my_dataset = Dataset(input_file=my_file_object)
```

If an *input\_file* keyword is provided, all other input is ignored. The *Dataset* plain-text representation format is as follows:

```
# x data
x_1  sigma_x_1
x_2  sigma_x_2  cor_x_12
...  ...      ...      ...
x_N  sigma_x_N  cor_x_1N  ...  cor_x_NN

# y data
y_1  sigma_y_1
y_2  sigma_y_2  cor_y_12
...  ...      ...      ...
y_N  sigma_y_N  cor_y_1N  ...  cor_y_NN
```

Here, the *sigma\_...* represents the statistical error of the data point and *cor\_...\_ij* is the correlation coefficient between the *i*-th and *j*-th data point.

Alternatively, field data can be set by passing iterables as keyword arguments. Available keywords for this purpose are:

#### **data**

a tuple/list of measurement data. Each element of the tuple/list must be iterable and be of the same length. The first element of the **data** tuple/list is assumed to be the *x* data, and the second to be the *y* data:

```
>>> my_dataset = Dataset(data=([0., 1., 2., 3., 4.], [1.23, 3.45, 5.62, 7.88, 9.64]))
```

Alternatively, x-y value pairs can also be passed as **data**. The following is equivalent to the above:

```
>>> my_dataset = Dataset(data=([0.0, 1.23], [1.0, 3.45], [2.0, 5.62], [3.0, 7.88], [4.0, 9.64]))
```

In case the *Dataset* contains two data points, the ordering is ambiguous. In this case, the first ordering (*x* data first, then *y* data) is assumed.

#### **cov\_mats**

a tuple/list of two-dimensional iterables containing the covariance matrices for *x* and *y*, in that order. Covariance matrices can be any sort of two-dimensional NxN iterables, assuming N is the number of data points.

```
>>> my_dataset = Dataset(data=([0., 1., 2.], [1.23, 3.45, 5.62]), cov_mats=(my_cov_mat_x, my_cov_mat_y))
```

This keyword argument can be omitted, in which case covariance matrices of zero are assumed. To specify a covariance matrix for a single axis, replace the other with `None`.

```
>>> my_dataset = Dataset(data=([0., 1., 2.], [1.23, 3.45, 5.62]), cov_mats=(None, my_cov_mat
```

#### **title**

the name of the *Dataset*. If omitted, the *Dataset* will be given the generic name 'Untitled Dataset'.

#### **axis\_labels = None**

axis labels

#### **axis\_units = None**

units to assume for axis

#### **cov\_mat\_is\_regular** (*axis*)

Returns *True* if the covariance matrix for an axis is regular and *False* if it is singular.

**axis** [string or int] Axis for which to check for regularity of the covariance matrix. Can be 'x' or 'y'.

#### **cov\_mats = None**

list of covariance matrices

#### **data = None**

list containing measurement data (axis-ordering)

#### **get\_axis** (*axis\_alias*)

Get axis id from an alias.

**axis\_alias** Alias of the axis whose id should be returned. This is for example either '0' or 'x' for the x-axis (id 0).

#### **get\_cov\_mat** (*axis*, *fallback\_on\_singular=None*)

Get the error matrix for an axis.

**axis string or int** Axis for which to load the error matrix. Can be 'x' or 'y'. Type: string

**fallback\_on\_singular** [*numpy.matrix* or string] What to return if the matrix is singular. If this is *None* (default), the matrix is returned anyway. If this is a *numpy.matrix* object or similar, that is returned instead. Alternatively, the shortcuts 'identity' or 1 and 'zero' or 0 can be used to return the identity and zero matrix respectively.

#### **get\_data** (*axis*)

Get the measurement data for an axis.

**axis** Axis for which to get the measurement data. Can be 'x' or 'y'. Type: string

#### **get\_data\_span** (*axis*, *include\_errorBars=False*)

Get the data span for an axis. The data span is a tuple (*min*, *max*) containing the smallest and highest coordinates for an axis.

**axis** Axis for which to get the data span. Can be 'x' or 'y'. Type: string

**include\_errorBars** [bool] *True* if the returned span should be enlarged to contain the error bars of the smallest and largest datapoints (default: *False*) Type: boolean

#### **get\_formatted** (*format\_string='.06e'*, *delimiter='t'*)

Returns the dataset in a plain-text format which is human-readable and can later be used as an input file for the creation of a new *Dataset*. The format is as follows:

```
# x data
x_1  sigma_x_1
x_2  sigma_x_2  cor_x_12
...  ...      ...      ...
```

```

x_N  sigma_x_N  cor_x_1N  ...  cor_x_NN

# y data
y_1  sigma_y_1
y_2  sigma_y_2  cor_y_12
...  ...      ...      ...
y_N  sigma_y_N  cor_y_1N  ...  cor_y_NN

```

Here, the `x_i` and `y_i` represent the measurement data, the `sigma_?_i` are the statistical uncertainties of each data point, and the `cor_?_ij` are the correlation coefficients between the *i*-th and *j*-th data point.

If the `x` or `y` errors are not correlated, then the entire correlation coefficient matrix can be omitted. If there are no statistical uncertainties for an axis, the second column can also be omitted. A blank line is required at the end of each data block!

**format\_string** [string (optional)] A format string with which each entry will be rendered. Default is `' .06e'`, which means the numbers are represented in scientific notation with six significant digits.

**delimiter** [string (optional)] A delimiter used to separate columns in the output.

**get\_size()**

Get the size of the *Dataset*. This is equivalent to the length of the *x*-axis data.

**has\_correlations** (*axis*)

Returns *True* if the covariance matrix for an axis is regular and *False* if it is singular.

**axis** string or int Axis for which to check for regularity of the covariance matrix. Can be `'x'` or `'y'`.

**has\_errors** (*axis*)

Returns *True* if the covariance matrix for an axis is regular and *False* if it is singular.

**axis** string or int Axis for which to check for regularity of the covariance matrix. Can be `'x'` or `'y'`.

**n\_axes = None**

dimensionality of the *Dataset*. Currently, only 2D *Datasets* are supported

**n\_datapoints = None**

number of data points in the *Dataset*

**read\_from\_file** (*input\_file*)

Reads the *Dataset* object from a file.

**returns** [boolean] *True* if the read succeeded, *False* if not.

**set\_cov\_mat** (*axis*, *mat*)

Set the error matrix for an axis.

**axis** Axis for which to load the error matrix. Can be `'x'` or `'y'`.

**mat** Error matrix for the axis. Passing *None* unsets the error matrix. Type: *numpy.matrix* or *None*

**set\_data** (*axis*, *data*)

Set the measurement data for an axis.

**axis** Axis for which to set the measurement data. Can be `'x'` or `'y'`. Type: string

**data** Measurement data for axis. Type: any iterable

**write\_formatted** (*file\_path*, *format\_string*=''.06e', *delimiter*='t')

Writes the dataset to a plain-text file. For details on the format, see [get\\_formatted](#).

**file\_path** [string] Path of the file object to write. **WARNING:** *overwrites existing files!*

**format\_string** [string (optional)] A format string with which each entry will be rendered. Default is `' .06e'`, which means the numbers are represented in scientific notation with six significant digits.

**delimiter** [string (optional)] A delimiter used to separate columns in the output.

`kafe.dataset.build_dataset(xdata, ydata, **kwargs)`

This helper function creates a *Dataset* from a series of keyword arguments.

Valid keyword arguments are:

**xdata and ydata** These keyword arguments are mandatory and should be iterables containing the measurement data.

**error specification keywords** A valid keyword is composed of an axis (*x* or *y*), an error relativity specification (*abs* or *rel*) and error correlation type (*stat* or *syst*). The errors are then set as follows:

1. **For statistical errors:**

- if keyword argument is a *NumPy* array, the error list is set to that
- if keyword argument is a number, an error list with identical entries is generated

2. **For systematic errors:**

- keyword argument *must* be a single number. The global correlated error for the axis is then set to that.

So, for example:

```
>>> myDataset = build_dataset(..., yabsstat=0.3, yrelsyst=0.1)
```

creates a dataset where the statistical error of each *y* coordinate is set to 0.3 and the overall systematic error of *y* is set to 0.1.

`kafe.dataset.debug_print(message)`

## 1.1.4 file\_tools Module

`kafe.file_tools.parse_column_data(file_to_parse, field_order='x, y', delimiter='')`

Parses a file which contains measurement data in a one-measurement-per-row format. The field (column) order can be specified. It defaults to *x,y*. Valid field names are *'x, y, xabsstat, yabsstat, xrelstat, yrelstat, xabssyst*. Another valid field name is *ignore* which can be used to skip a field.

Every valid measurement data file *must* have an *x* and a *y* field.

Additionally, a delimiter can be specified. If this is a whitespace character or omitted, any sequence of whitespace characters is assumed to separate the data.

**file\_to\_parse** [file-like object or string containing a file path] The file to parse.

**field\_order** [string (optional)] A string of comma-separated field names giving the order of the columns in the file. Defaults to *'x, y'*.

**delimiter** [string (optional)] The field delimiter used in the file.

## 1.1.5 fit Module

`class kafe.fit.Fit(dataset, fit_function, external_fcn=<function chi2 at 0x3823de8>, function_label=None, function_equation=None)`

Object representing a fit. This object references the fitted *Dataset*, the fit function and the resulting fit parameters.

Necessary arguments are a *Dataset* object and a fit function (which should be fitted to the *Dataset*). Optionally, an external function *FCN* (whose minima should be located to find the best fit) can be specified. If not given, the *FCN* function defaults to  $\chi^2$ .

**dataset** [*Dataset*] A *Dataset* object containing all information about the data

**fit\_function** [function] A user-defined Python function to be fitted to the data. This function's first argument must be the independent variable  $x$ . All other arguments *must* be named and have default values given. These defaults are used as a starting point for the actual minimization. For example, a simple linear function would be defined like:

```
>>> def linear_2par(x, slope=1, y_intercept=0):  
...     return slope * x + y_intercept
```

Be aware that choosing sensible initial values for the parameters is often crucial for a successful fit, particularly for functions of many parameters.

**external\_fcn** [function (optional)] An external *FCN* (function to minimize). This function must have the following call signature:

```
>>> FCN(xdata, ydata, cov_mat, fit_function, param_values)
```

It should return a float. If not specified, the default  $\chi^2$  *FCN* is used. This should be sufficient for most fits.

**function\_label** [L<sup>A</sup>T<sub>E</sub>X-formatted string (optional)] A name/label/short description of the fit function. This appears in the legend describing the fitter curve. If omitted, this defaults to the function's Python name.

**function\_equation** [L<sup>A</sup>T<sub>E</sub>X-formatted string (optional)] The fit function's equation.

**call\_external\_fcn** (\**param\_values*)

Wrapper for the external *FCN*. Since the actual fit process depends on finding the right parameter values and keeping everything else constant, we can use the *Dataset* object to pass known, fixed information to the external *FCN*, varying only the parameter values.

**param\_values** [sequence of values] the parameter values at which *FCN* is to be evaluated

**do\_fit** (*quiet=False*, *verbose=False*)

Runs the fit algorithm for this *Fit* object.

First, the *Dataset* is fitted considering only uncertainties in the  $y$  direction. If the *Dataset* has no uncertainties in the  $y$  direction, they are assumed to be equal to 1.0 for this preliminary fit, as there is no better information available.

Next, the fit errors in the  $x$  direction (if they exist) are taken into account by projecting the covariance matrix for the  $x$  errors onto the  $y$  covariance matrix. This is done by taking the first derivative of the fit function in each point and “projecting” the  $x$  error onto the resulting tangent to the curve.

This last step is repeated until the change in the error matrix caused by the projection becomes negligible.

**quiet** [boolean] Set to `True` if no output should be printed.

**verbose** [boolean] Set to `True` if more output should be printed.

**fit\_one\_iteration** (*verbose=False*)

Instructs the minimizer to do a minimization.

**get\_current\_fit\_function**()

This method returns a function object corresponding to the fit function for the current parameter values. The returned function is a function of a single variable.

**returns** [function] A function of a single variable corresponding to the fit function at the current parameter values.

**get\_error\_matrix**()

This method returns the covariance matrix of the fit parameters which is obtained by querying the minimizer object for this fit

**returns** [*numpy.matrix*] The covariance matrix of the parameters.

**get\_parameter\_errors** (*rounding=False*)

Get the current parameter uncertainties from the minimizer.

**rounding** [boolean] Whether or not to round the returned values to significance.

**returns** [tuple] A tuple of the parameter uncertainties

**get\_parameter\_values** (*rounding=False*)

Get the current parameter values from the minimizer.

**rounding** [boolean] Whether or not to round the returned values to significance.

**returns** [tuple] A tuple of the parameter values

**print\_fit\_details** ()

prints some fit goodness details

**print\_fit\_results** ()

prints fit results

**print\_rounded\_fit\_parameters** ()

prints the fit parameters

**project\_x\_covariance\_matrix** ()

Project the  $x$  errors from the  $x$  covariance matrix onto the total matrix.

This is done elementwise, according to the formula:

$$C_{\text{tot},ij} = C_{y,ij} + C_{x,ij} \frac{\partial f}{\partial x_i} \frac{\partial f}{\partial x_j}$$

`kafe.fit.chi2(xdata, ydata, cov_mat, fit_function, param_values)`

A simple  $\chi^2$  implementation. Calculates  $\chi^2$  according to the formula:

$$\chi^2 = \lambda^T C^{-1} \lambda$$

Here,  $\lambda$  is the residual vector  $\lambda = \vec{y} - \vec{f}(\vec{x})$  and  $C$  is the covariance matrix.

**xdata** [iterable] The  $x$  measurement data

**ydata** [iterable] The  $y$  measurement data

**cov\_mat** [*numpy.matrix*] The total covariance matrix

**fit\_function** [function] The fit function  $f(x)$

**param\_values** [list/tuple] The values of the parameters at which  $f(x)$  should be evaluated.

`kafe.fit.round_to_significance(value, error, significance=2)`

Rounds the error to the established number of significant digits, then rounds the value to the same order of magnitude as the error.

**value** [float] value to round to significance

**error** [float] uncertainty of the value

**significance** [int (optional)] number of significant digits of the error to consider

## 1.1.6 function\_tools Module

`kafe.function_tools.derivative(func, derive_by_index, variables_tuple, derivative_spacing)`

Gives  $\frac{\partial f}{\partial x_k}$  for  $f = f(x_0, x_1, \dots)$ . *func* is  $f$ , *variables\_tuple* is  $\{x_i\}$  and *derive\_by\_index* is  $k$ .

`kafe.function_tools.derive_by_parameters` (*func*, *x\_0*, *param\_list*, *derivative\_spacing*)  
Returns the gradient of *func* with respect to its parameters, i.e. with respect to every variable of *func* except the first one.

`kafe.function_tools.derive_by_x` (*func*, *x\_0*, *param\_list*, *derivative\_spacing*)  
If *x\_0* is iterable, gives the array of derivatives of a function  $f(x, par_1, par_2, \dots)$  around  $x = x_i$  at every  $x_i$  in  $\vec{x}$ . If *x\_0* is not iterable, gives the derivative of a function  $f(x, par_1, par_2, \dots)$  around  $x = x_0$ .

`kafe.function_tools.get_function_property` (*func*, *prop*)  
Returns a specific property of the function. This assumes that the function is defined as

```
>>> def func(x, par1=1.0, par2=3.14, par3=2.71, ...): ...
```

**func** [function] A function object from which to extract the property.

**prop** [any of 'name', 'parameter names', 'parameter defaults', 'number of parameters'] A string representing a property.

`kafe.function_tools.outer_product` (*input\_array*)  
Takes a *NumPy* array and returns the outer (dyadic, Kronecker) product with itself. If *input\_array* is a vector  $\mathbf{x}$ , this returns  $\mathbf{xx}^T$ .

### 1.1.7 minuit Module

**class** `kafe.minuit.Minuit` (*number\_of\_parameters*, *function\_to\_minimize*, *par\_names*, *start\_params*, *param\_errors*, *quiet=True*, *verbose=False*)

Bases: object

A class for communicating with ROOT's function minimizer tool Minuit.

**FCN\_wrapper** (*number\_of\_parameters*, *derivatives*, *f*, *parameters*, *internal\_flag*)

This is actually a function called in ROOT and acting as a C wrapper for our B{FCN}, which is implemented in Python.

This function is called by Minuit several times during a fit. It doesn't return anything but sets/modifies one of its arguments (*f*). This is ugly. Its argument structure is fixed and determined by Minuit:

@param *number\_of\_parameters*: The number of parameters of the current fit @type *number\_of\_parameters*: int

@param *derivatives*: computed gradient ?? @type *derivatives*: ??

@param *f*: A (C-compatible) array. The desired function value is in *f*[0] after execution. @type *f*: array

@param *parameters*: A C array of parameters. Is cast to a Python list @type *parameters*: array

@param *internal\_flag*: A flag allowing for different behaviour of the function @type *internal\_flag*: any int from M{1} (initial run) to M{4} (normal run)

**get\_chi2\_probability** (*n\_deg\_of\_freedom*)

Returns the probability that an observed  $S\{\chi\}$ -square exceeds the calculated value of  $S\{\chi\}$ -square for this fit by chance, even for a correct model. In other words, returns the probability that a worse fit of the model to the data exists. If this is a small value (typically  $M\{< 5\%\}$ ), this means the fit is pretty bad. For values below this threshold, the model very probably does not fit the data.

**get\_error\_matrix** ()

Retrieves the parameter error matrix from TMinuit

**get\_fit\_info** (*info*)

Retrieves other info from Minuit. The argument *info* can be any of the following: - *fcn*: FCN value at

minimum, - *edm*: estimated distance to minimum - *err\_def*: *Minuit* error matrix status code - *status\_code*: *Minuit* general status code

**get\_parameter\_errors** ()

Retrieves the parameter errors from TMinuit. Returns a tuple.

**get\_parameter\_info** ()

Retrieves parameter information from TMinuit. Returns a list of tuples (param\_name, param\_val, param\_error)

**get\_parameter\_name** (param\_nr)

Sets the fit parameters. If param\_values='None', tries to infer defaults from the function\_to\_minimize.

**get\_parameter\_values** ()

Retrieves the parameter values from TMinuit. Returns a tuple.

**minimize** ()

Do the minimization

**reset** ()

**set\_err** (up\_value=1.0)

Sets the UP value for Minuit. Default: 1.0 (good for chi2)

**set\_parameter\_errors** (param\_errors=None)

Sets the fit parameter errors. If param\_values='None', sets the error to 1% of the parameter value.

**set\_parameter\_names** (param\_names)

Sets the fit parameters. If param\_values='None', tries to infer defaults from the function\_to\_minimize.

**set\_parameter\_values** (param\_values)

Sets the fit parameters. If param\_values='None', tries to infer defaults from the function\_to\_minimize.

**set\_print\_level** (print\_level=3)

Sets the print level for Minuit. Default: 0 (suppress all output)

**set\_strategy** (strategy\_id=1)

Sets the strategy Minuit. Default: 1 (optimized)

## 1.1.8 numeric\_tools Module

`kafe.numeric_tools.cor_to_cov` (cor\_mat, error\_list)

Converts a correlation matrix to a covariance matrix according to the formula

$$\text{Cov}_{ij} = \text{Cor}_{ij} \sigma_i \sigma_j$$

**cor\_mat** [*numpy.matrix*] The correlation matrix to convert.

**error\_list** [sequence of floats] A sequence of statistical errors. Must be of the same length as the diagonal of *cor\_mat*.

`kafe.numeric_tools.cov_to_cor` (cov\_mat)

Converts a covariance matrix to a correlation matrix according to the formula

$$\text{Cor}_{ij} = \frac{\text{Cov}_{ij}}{\sqrt{\text{Cov}_{ii} \text{Cov}_{jj}}}$$

**cov\_mat** The covariance matrix to convert. Type: *numpy.matrix*

`kafe.numeric_tools.extract_statistical_errors` (cov\_mat)

Extracts the statistical errors from a covariance matrix. This means it returns the (elementwise) square root of the diagonal entries

**cov\_mat** The covariance matrix to extract errors from. Type: *numpy.matrix*

`kafe.numeric_tools.make_symmetric_lower(mat)`

Copies the matrix entries below the main diagonal to the upper triangle half of the matrix. Leaves the diagonal unchanged. Returns a *NumPy* matrix object.

**mat** [*numpy.matrix*] A lower diagonal matrix.

**returns** [*numpy.matrix*] The lower triangle matrix.

`kafe.numeric_tools.zero_pad_lower_triangle(triangle_list)`

Converts a list of lists into a lower triangle matrix. The list members should be lists of increasing length from 1 to N, N being the dimension of the resulting lower triangle matrix. Returns a *NumPy* matrix object.

For example:

```
>>> zero_pad_lower_triangle([ [1.0], [0.2, 1.0], [0.01, 0.4, 3.0] ])
matrix([[ 1. ,  0. ,  0. ],
        [ 0.2 ,  1. ,  0. ],
        [ 0.01,  0.4 ,  3. ]])
```

**triangle\_list** [list] A list containing lists of increasing length.

**returns** [*numpy.matrix*] The lower triangle matrix.

### 1.1.9 plot Module

`class kafe.plot.Plot (*fits, **kwargs)`

**compute\_plot\_range** (*include\_errorBars=True*)

Compute the span of all child datasets and sets the plot range to that

**extend\_span** (*axis, new\_span*)

Expand the span of the current plot.

This method extends the current plot span to include *new\_span*

**init\_plots** ()

Initialize the plots for each fit.

**plot** (*p\_id*)

Plot the *Fit* object with the number *p\_id* to its figure.

**plot\_all** ()

Plot every *Fit* object to its figure.

**save** (*output\_file*)

Save the *Plot* to a file.

**show** ()

Show the *Plot* in a matplotlib interactive window.

`class kafe.plot.PlotStyle`

Class for specifying a style for a specific plot. This object stores a progression of marker and line types and colors, as well as preferences relating to point size and label size. These can be overridden by overwriting the instance variables directly. A series of *get\_...* methods are provided which go through these lists cyclically.

**get\_line** (*idm*)

Get a specific line type. This runs cyclically through the defined defaults.

**get\_linecolor** (*idm*)

Get a specific line color. This runs cyclically through the defined defaults.

**get\_marker** (*idm*)

Get a specific marker type. This runs cyclically through the defined defaults.

**get\_markercolor** (*idm*)

Get a specific marker color. This runs cyclically through the defined defaults.

**get\_pointsize** (*idm*)

Get a specific point size. This runs cyclically through the defined defaults.

`kafe.plot.pad_span` (*span*, *pad\_coeff*=1, *additional\_pad*=None)

Enlarges the interval *span* (list of two floats) symmetrically around its center to length *pad\_coeff*. Optionally, an *additional\_pad* argument can be specified. The returned span is then additionally enlarged by that amount.

*additional\_pad* can also be a list of two floats which specifies an asymmetric amount by which to enlarge the span. Note that in this case, positive entries in *additional\_pad* will enlarge the span (move the interval end away from the interval's center) and negative amounts will shorten it (move the interval end towards the interval's center).

## A

axis\_labels (kafe.dataset.Dataset attribute), 5  
axis\_units (kafe.dataset.Dataset attribute), 5

## B

build\_dataset() (in module kafe.dataset), 7

## C

call\_external\_fcn() (kafe.fit.Fit method), 8  
chi2() (in module kafe.fit), 9  
compute\_plot\_range() (kafe.plot.Plot method), 12  
constants (module), 3  
cor\_to\_cov() (in module kafe.numeric\_tools), 11  
cov\_mat\_is\_regular() (kafe.dataset.Dataset method), 5  
cov\_mats (kafe.dataset.Dataset attribute), 5  
cov\_to\_cor() (in module kafe.numeric\_tools), 11

## D

data (kafe.dataset.Dataset attribute), 5  
Dataset (class in kafe.dataset), 4  
dataset (module), 4  
debug\_print() (in module kafe.dataset), 7  
derivative() (in module kafe.function\_tools), 9  
derive\_by\_parameters() (in module kafe.function\_tools), 9  
derive\_by\_x() (in module kafe.function\_tools), 10  
do\_fit() (kafe.fit.Fit method), 8

## E

extend\_span() (kafe.plot.Plot method), 12  
extract\_statistical\_errors() (in module kafe.numeric\_tools), 11

## F

F\_SIGNIFICANCE (in module kafe.constants), 3  
FCN\_wrapper() (kafe.minuit.Minuit method), 10  
file\_tools (module), 7  
Fit (class in kafe.fit), 7  
fit (module), 7  
fit\_one\_iteration() (kafe.fit.Fit method), 8  
function\_tools (module), 9

## G

G\_PADDING\_FACTOR\_X (in module kafe.constants), 3  
G\_PADDING\_FACTOR\_Y (in module kafe.constants), 3  
G\_PLOT\_POINTS (in module kafe.constants), 3  
get\_axis() (kafe.dataset.Dataset method), 5  
get\_chi2\_probability() (kafe.minuit.Minuit method), 10  
get\_cov\_mat() (kafe.dataset.Dataset method), 5  
get\_current\_fit\_function() (kafe.fit.Fit method), 8  
get\_data() (kafe.dataset.Dataset method), 5  
get\_data\_span() (kafe.dataset.Dataset method), 5  
get\_error\_matrix() (kafe.fit.Fit method), 8  
get\_error\_matrix() (kafe.minuit.Minuit method), 10  
get\_fit\_info() (kafe.minuit.Minuit method), 10  
get\_formatted() (kafe.dataset.Dataset method), 5  
get\_function\_property() (in module kafe.function\_tools), 10  
get\_line() (kafe.plot.PlotStyle method), 12  
get\_linecolor() (kafe.plot.PlotStyle method), 12  
get\_marker() (kafe.plot.PlotStyle method), 13  
get\_markercolor() (kafe.plot.PlotStyle method), 13  
get\_parameter\_errors() (kafe.fit.Fit method), 9  
get\_parameter\_errors() (kafe.minuit.Minuit method), 11  
get\_parameter\_info() (kafe.minuit.Minuit method), 11  
get\_parameter\_name() (kafe.minuit.Minuit method), 11  
get\_parameter\_values() (kafe.fit.Fit method), 9  
get\_parameter\_values() (kafe.minuit.Minuit method), 11  
get\_pointsize() (kafe.plot.PlotStyle method), 13  
get\_size() (kafe.dataset.Dataset method), 6

## H

has\_correlations() (kafe.dataset.Dataset method), 6  
has\_errors() (kafe.dataset.Dataset method), 6

## I

init\_plots() (kafe.plot.Plot method), 12

## K

kafe.\_\_init\_\_ (module), 3  
kafe.constants (module), 3  
kafe.dataset (module), 4  
kafe.file\_tools (module), 7

kafe.fit (module), 7  
kafe.function\_tools (module), 9  
kafe.minuit (module), 10  
kafe.numeric\_tools (module), 11  
kafe.plot (module), 12

## M

M\_CONFIDENCE\_LEVEL (in module kafe.constants), 3  
M\_MAX\_ITERATIONS (in module kafe.constants), 3  
M\_MAX\_X\_FIT\_ITERATIONS (in module kafe.constants), 3  
M\_TOLERANCE (in module kafe.constants), 3  
make\_symmetric\_lower() (in module kafe.numeric\_tools), 12  
minimize() (kafe.minuit.Minuit method), 11  
Minuit (class in kafe.minuit), 10  
minuit (module), 10

## N

n\_axes (kafe.dataset.Dataset attribute), 6  
n\_datapoints (kafe.dataset.Dataset attribute), 6  
numeric\_tools (module), 11

## O

outer\_product() (in module kafe.function\_tools), 10

## P

pad\_span() (in module kafe.plot), 13  
parse\_column\_data() (in module kafe.file\_tools), 7  
Plot (class in kafe.plot), 12  
plot (module), 12  
plot() (kafe.plot.Plot method), 12  
plot\_all() (kafe.plot.Plot method), 12  
PlotStyle (class in kafe.plot), 12  
print\_fit\_details() (kafe.fit.Fit method), 9  
print\_fit\_results() (kafe.fit.Fit method), 9  
print\_rounded\_fit\_parameters() (kafe.fit.Fit method), 9  
project\_x\_covariance\_matrix() (kafe.fit.Fit method), 9

## R

read\_from\_file() (kafe.dataset.Dataset method), 6  
reset() (kafe.minuit.Minuit method), 11  
round\_to\_significance() (in module kafe.fit), 9

## S

save() (kafe.plot.Plot method), 12  
set\_cov\_mat() (kafe.dataset.Dataset method), 6  
set\_data() (kafe.dataset.Dataset method), 6  
set\_err() (kafe.minuit.Minuit method), 11  
set\_parameter\_errors() (kafe.minuit.Minuit method), 11  
set\_parameter\_names() (kafe.minuit.Minuit method), 11  
set\_parameter\_values() (kafe.minuit.Minuit method), 11

set\_print\_level() (kafe.minuit.Minuit method), 11  
set\_strategy() (kafe.minuit.Minuit method), 11  
show() (kafe.plot.Plot method), 12

## W

write\_formatted() (kafe.dataset.Dataset method), 6

## Z

zero\_pad\_lower\_triangle() (in module kafe.numeric\_tools), 12
